HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

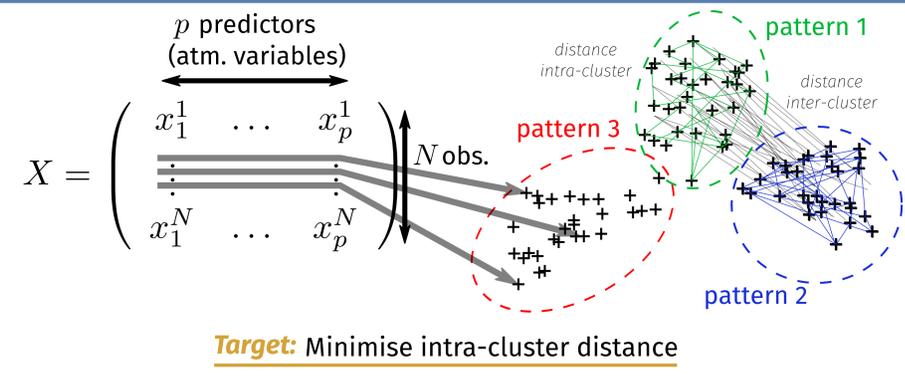

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Presented at *Journée scientifique du SIRTA*, 15/06/2018

Abstract

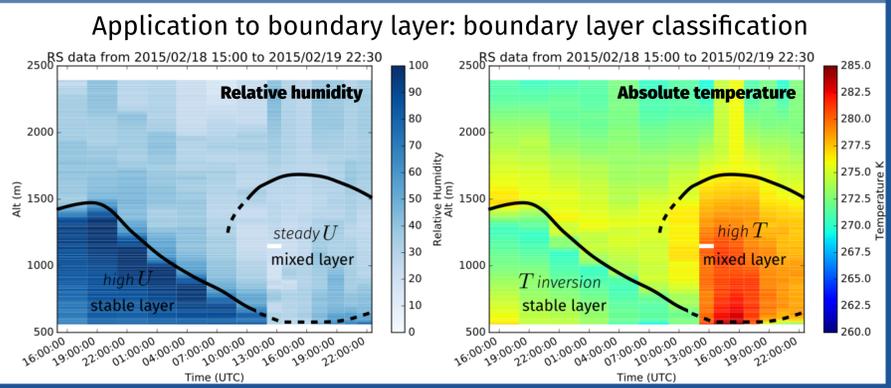

Unsupervised learning aims to derive high level information from data without reference. This work shows an example of how it can be used to derive user information from field campaign measurements. Three algorithms have been tested on their ability to make a good boundary layer classification: *K-means*, *Agglomerative* and *DBSCAN*. Data are from radiosoundings in the 2nd IOP of the Passy-2015 field experiment (alpine valley, wintertime). One can see a stable layer, a mixed layer and the free atmosphere. Agglomerative gives the best results and has promising prospects. *K-means* and *DBSCAN* give clusters not corresponding to visual examination, but both have many ways of improvement.

1 Introduction

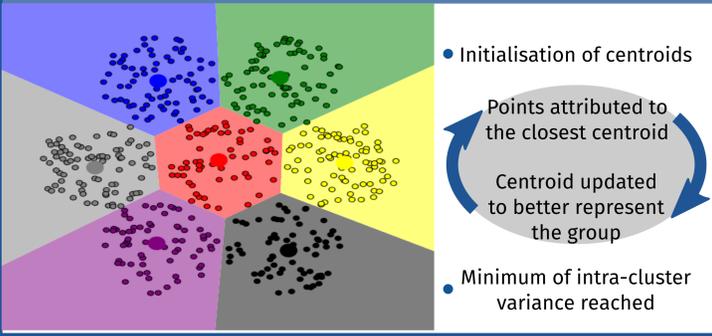

All methods look for high density areas with a **dissimilarity metric**

- problem-dependent questions
- Which predictors?
Here: normalized z, t, T, U
 - Which dissimilarity?
Here: squared gap

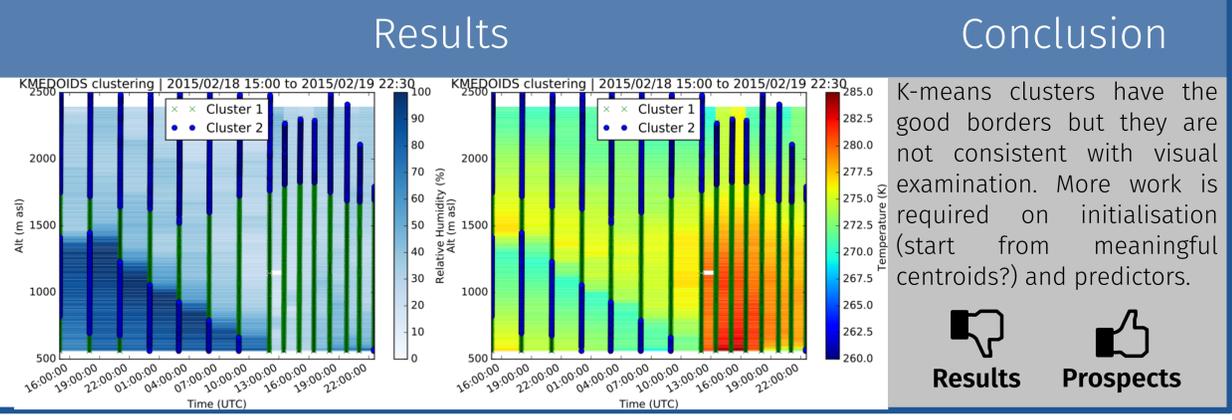

2 K-means clustering

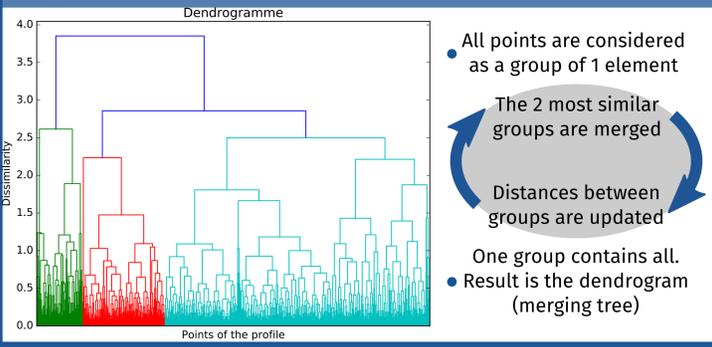

- Fast convergence (few 10 iterations)
- Different strategies of initialisation

- Converges toward a local minimum
- Initialisation highly influences the result
- Choice of the number of groups?

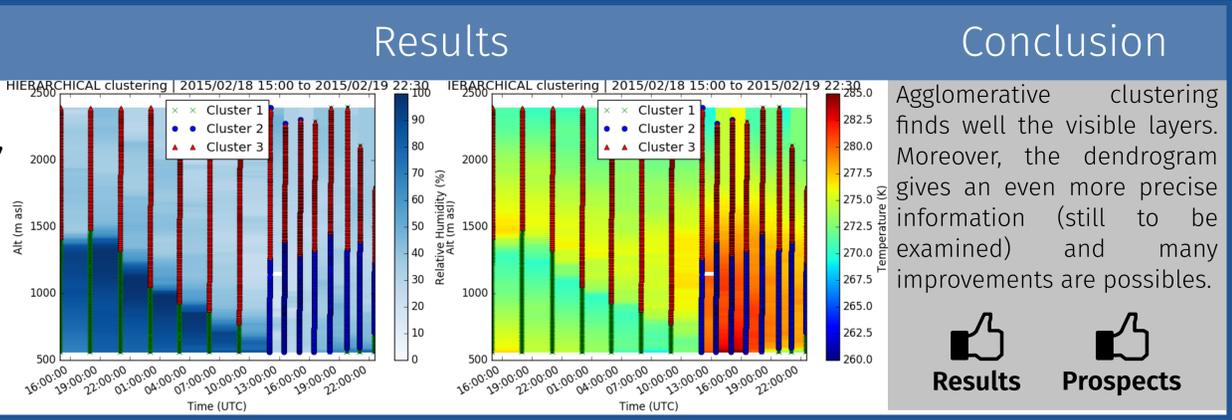

3 Agglomerative clustering

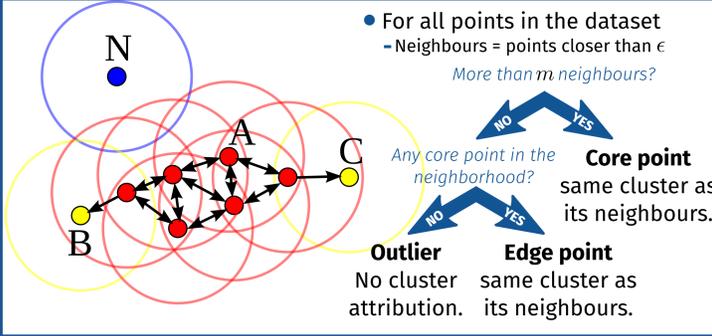

- Can highlight a "natural" number of groups
- Nested clusters (identify smaller scale structures?)
- No parameter to tune
- Graphical summary of results in dendrogram

- Gives hierarchical structure anyway, regardless whether it is relevant
- Small changes in data can lead to different dendrogram
- Choice of linkage?
- Prohibitive cost when large dataset

4 DBSCAN clustering

- Automatically find the number of groups
- Clusters can be of any shape
- Resilient to outliers (can even identify them)

- Edge points connected to more than one cluster can change assignation depending on their ordering
- Clusters must be of similar density
- Choice of the parameters m and ϵ ?
